

Ex: Compute $\int_C (3y - e^{\sin(x)}) dx + (7x + \sqrt{y^4+1}) dy$ for C the picture.

Circle $x^2 + y^2 = 9$

solve: $\int_{\partial D} (3y - e^{\sin(x)}) dx + (7x + \sqrt{y^4+1}) dy$

$$= \iint_D \left(\frac{\partial}{\partial x} (7x + \sqrt{y^4+1}) - \frac{\partial}{\partial y} (3y - e^{\sin(x)}) \right) dA$$

$$= \iint_D 7 - 3 dA = 4 \iint_D dA \quad 4 \cdot (\pi(3)^2) = 36\pi$$

Last time's Green's Theorem

Proposition (Green's Theorem): Suppose D a connected region in the plane with ∂D a smooth simple closed curve. If $P(x,y)$ and $Q(x,y)$ have continuous partial derivatives on some open region R containing

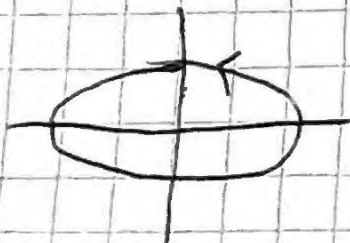

D , then

$$\int_{\partial D} P dx + Q dy = \iint_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA$$

Ex: Compute $\int_C y^4 dx + 2xy^2 dy$ for C the ellipse $x^2 + 2y^2 = 2$

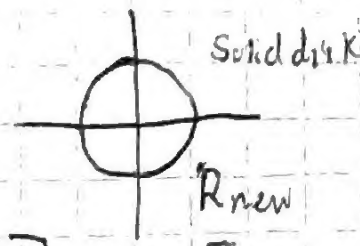

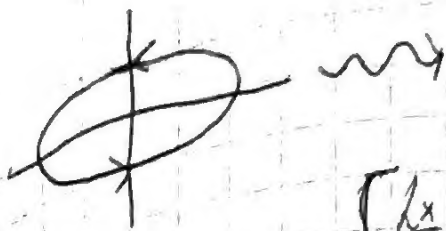

Solution: $\int_C y^4 dx + 2xy^2 dy = \iint_D \left(\frac{\partial}{\partial x} [2xy] - \frac{\partial}{\partial y} [y^4] \right) dA$ $D = \text{"solid ellipse"}$

$$\begin{cases} x = \sqrt{2}r \cos(\theta) \\ y = r \sin(\theta) \end{cases} \text{ for } \begin{cases} 0 \leq r \leq 1 \\ 0 \leq \theta \leq 2\pi \end{cases}$$

$$x^2 + 2y^2 = 2 \Rightarrow 2r^2 \cos^2(\theta) + 2r^2 \sin^2(\theta) = 2 \Rightarrow$$

$$r^2 = 1 \Rightarrow r = 1$$

$$\frac{d(x,y)}{d(r,\theta)} = \text{determinant} \begin{bmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial \theta} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial \theta} \end{bmatrix} = \det \begin{bmatrix} \sqrt{2} \cos(\theta) & -\sqrt{2} r \sin(\theta) \\ \sin(\theta) & r \cos(\theta) \end{bmatrix} \Rightarrow$$

$$= \sqrt{2} r \cos^2(\theta) - \sqrt{2} r \sin^2(\theta) = \sqrt{2} r$$

$$\iint_D (2y^2 - 4y^3) dA = \int_{r=0}^1 \int_{\theta=0}^{2\pi} (2(r \sin(\theta))^2 - 4(r \sin(\theta))^3) \cdot \sqrt{2} r d\theta dr$$

$$= \int_{r=0}^1 \int_{\theta=0}^{2\pi} 2\sqrt{2} r^3 (\sin^2(\theta) - 2r \sin^3(\theta)) d\theta dr = \int_{r=0}^1 \int_{\theta=0}^{2\pi} 2\sqrt{2} r^3 \sin^2(\theta) (1 - 2r \sin(\theta)) d\theta dr$$

$$= \int_{r=0}^1 2\sqrt{2} r^3 \int_{\theta=0}^{2\pi} (1 - \cos^2(\theta)) (1 - 2r \sin(\theta)) d\theta dr$$

$$u = \cos(\theta) \\ du = -\sin(\theta) d\theta$$

$$\Rightarrow \int_{\theta=0}^{2\pi} (1 - \cos^2(\theta)) (1 - 2r \sin(\theta)) d\theta \Rightarrow \int_{\theta=0}^{2\pi} 1 - \cos^2(\theta) d\theta - \int_{\theta=0}^{2\pi} 2r(1 - \cos^2(\theta)) \sin(\theta) d\theta$$

$$= \int_{\theta=0}^{2\pi} (1 - (\frac{1}{2}(1 + \cos(2\theta))) d\theta - 2r \int_{\theta=0}^{2\pi} (1 - u^2) du \Rightarrow \cos^2(\theta) = \frac{1}{2}(1 + \cos(2\theta))$$

$$= \int_{\theta=0}^{2\pi} (\frac{1}{2} - \frac{1}{2} \cos(2\theta)) d\theta + 2r [u - \frac{1}{3} u^3]_{\theta=0}^{2\pi} \Rightarrow$$

$$= [\frac{1}{2}(\theta - \frac{1}{2} \sin(2\theta))]_{\theta=0}^{2\pi} + 2r [\cos(\theta) - \frac{1}{3} \cos^3(\theta)]_{\theta=0}^{2\pi} \Rightarrow$$

Next Page

$$= \left(\frac{1}{2} (2\pi - 0) - \frac{1}{4} (\sin(4\pi) - \sin(0)) + 2r((\ln(2\pi) - \ln(0))) - \frac{1}{3} (\ln^3(2\pi) - \ln^3(0)) \right)$$

$$= \pi - \frac{1}{4}(0) - 2r(0 - \frac{1}{3} \cdot 0) = \pi$$

Outer Integral

$$\int_{r=0}^1 2\sqrt{2} r^3 \pi dr = \frac{2\sqrt{2}\pi}{4} [r^4]_{r=0}^1 = \frac{\pi}{\sqrt{2}} (1-0) = \frac{\pi}{\sqrt{2}}$$

$$\therefore \int_C y^4 dx + 2xy^2 dy = \frac{\pi}{\sqrt{2}}$$

Note: The way we've been using Green's theorem has been turn a line integral into a double integral. But we can go the other way.

If our double Integral's region is "nice enough," then we can turn our double Integral into a line integral.

Note: If P and Q satisfy $\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 1$ then

$$\text{Area}(D) = \iint_D 1 dA = \iint_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA = \int_{\partial D} P dx + Q dy$$

Ex. Compute the area of the general ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$

Solution: $\text{Area}(D) = \int_D P dx + Q dy$ when P, Q satisfy $\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 1$

Choose $Q(x,y) = x$ and $P(x,y) = 0$ then $\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = \frac{\partial}{\partial x}[x] - \frac{\partial}{\partial y}[0] = 1$

$$\therefore \text{Area}(D) = \int_{\partial D} 0 dx + x dy = \int_{\partial D} x dy$$

AP is parameterized by $\vec{r}(\theta) = \langle a \cos(\theta), b \sin(\theta) \rangle$ on $0 \leq \theta \leq 2\pi$

$$\therefore \text{Area}(D) = \int_{AP} x \, dy = \int_{\theta=0}^{2\pi} a \cos(\theta) b \sin(\theta) d\theta = ab \int_{\theta=0}^{2\pi} \cos^2(\theta) d\theta \Rightarrow$$

$$ab \int_{\theta=0}^{2\pi} \frac{1}{2} (1 + \cos(2\theta)) d\theta \Rightarrow ab \int_{\theta=0}^{2\pi} \frac{1}{2} \left[\theta + \frac{1}{2} \sin(2\theta) \right]_{\theta=0}^{2\pi} \Rightarrow$$

$$\frac{1}{2} ab ((2\pi - 0) + \frac{1}{2} (0 - 0)) = ab\pi$$

16.5: Curl and Divergence

Goal: Define and study two new operations on vector fields.

Definition: The curl of a vector field \vec{v} on \mathbb{R}^3 is the vector field

$$\nabla \times \vec{v} = \left\langle \frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z} \right\rangle \times \vec{v} = \left\langle \frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z} \right\rangle \times \langle P, Q, R \rangle$$

$$= \text{determinant} \begin{bmatrix} \vec{i} & \vec{j} & \vec{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ P & Q & R \end{bmatrix} = \left\langle \frac{\partial R}{\partial y} - \frac{\partial Q}{\partial z}, -\left(\frac{\partial R}{\partial x} - \frac{\partial P}{\partial z}\right), \frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right\rangle$$

Ex: Compute $\text{curl}(\vec{v})$ for $\vec{v} = \langle xy, xyz, -y^2 \rangle$

$$\text{curl}(\vec{v}) = \nabla \times \vec{v} = \text{determinant} \begin{bmatrix} \vec{i} & \vec{j} & \vec{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ xy & xyz & -y^2 \end{bmatrix} = \left\langle \frac{\partial}{\partial y}[-y^2] - \frac{\partial}{\partial z}[xyz], -\left(\frac{\partial}{\partial x}[-y^2] - \frac{\partial}{\partial z}[xy]\right), \frac{\partial}{\partial x}[xyz] - \frac{\partial}{\partial y}[xy] \right\rangle$$

$$= \langle -2y - xy, 0, yz - x \rangle$$

Observation: If $\vec{v} = \nabla f$ is a conservative vector field, then $\vec{v} = \langle f_x, f_y, f_z \rangle$

$$\text{and } \text{curl}(\vec{v}) = \nabla \times \vec{v} = \text{determinant} \begin{bmatrix} \vec{i} & \vec{j} & \vec{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ f_x & f_y & f_z \end{bmatrix} \quad (\text{Converse is true})$$

$$= \langle f_{xy} - f_{yz}, -(f_{xz} - f_{zx}), f_{yx} - f_{xy} \rangle = \vec{0} \text{ by Clairaut's theorem}$$

Point: A vector field \vec{v} is conservative if and only if $\text{Curl}(\vec{v}) = \vec{0}$

Definition: The divergence of vector field $\vec{v} = \langle v_1, v_2, \dots, v_n \rangle$

$$\text{div}(\vec{v}) = \nabla \cdot \vec{v} = \left\langle \frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2}, \dots, \frac{\partial}{\partial x_n} \right\rangle \cdot \langle v_1, v_2, \dots, v_n \rangle \\ = \left\langle \frac{\partial v_1}{\partial x_1}, \frac{\partial v_2}{\partial x_2}, \dots, \frac{\partial v_n}{\partial x_n} \right\rangle$$

Ex:

$$\text{Ex: } \text{div}(\langle xy, xyz, -y^2 \rangle) =$$

$$= \nabla \cdot \langle xy, xyz, -y^2 \rangle = \frac{\partial}{\partial x} [xy] + \frac{\partial}{\partial y} [xyz] + \frac{\partial}{\partial z} [-y^2]$$

$$= y + xz + 0 = y + xz$$

Proposition: A vector field \vec{v} is the curl of some vector field \vec{w}

if and only if $\text{div}(\vec{v}) = 0$

(\Rightarrow): If $\vec{v} = \text{curl}(\langle P, Q, R \rangle)$, then we have

$$\vec{v} = \left\langle \frac{\partial R}{\partial y} - \frac{\partial Q}{\partial z}, \left(\frac{\partial R}{\partial x} - \frac{\partial P}{\partial z} \right), \frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right\rangle$$

$$\text{Then } \text{div}(\vec{v}) = \nabla \cdot \vec{v} = \frac{\partial}{\partial x} [R_y - Q_z] + \frac{\partial}{\partial y} [P_z - R_x] + \frac{\partial}{\partial z} [Q_x - P_y]$$

$$= R_{yx} - Q_{zx} + P_{zy} - R_{xy} + Q_{yz} - P_{xz}$$

$$= (R_{yx} - R_{xy}) + (P_{yz} - P_{zy}) + (Q_{xz} - Q_{zx}) = 0 + 0 + 0 = 0$$

by Clairaut's theorem

Point: Proposition can be used to check if a vector field is a curl.
